**Algorithm 1:** Tucker-ALS for Fully Observable Tensors (HOOI)

---

**Input :** Tensor  $\mathcal{X} \in \mathbb{R}^{I_1 \times I_2 \times \dots \times I_N}$ , and core tensor dimensionality  $J_1, \dots, J_N$ .  
**Output:** Factor matrices  $\mathbf{A}^{(n)} \in \mathbb{R}^{I_n \times J_n}$  ( $n = 1, \dots, N$ ), and core tensor  $\mathcal{G} \in \mathbb{R}^{J_1 \times J_2 \times \dots \times J_N}$ .

- 1 initialize all factor matrices  $\mathbf{A}^{(n)}$
- 2 **repeat**
- 3     **for**  $n = 1 \dots N$  **do**
- 4          $\mathcal{Y} \leftarrow \mathcal{X} \times_1 \mathbf{A}^{(1)\top} \dots \times_{n-1} \mathbf{A}^{(n-1)\top} \times_{n+1}$   
            $\mathbf{A}^{(n+1)\top} \dots \times_N \mathbf{A}^{(N)\top}$
- 5          $\mathbf{A}^{(n)} \leftarrow J_n$  leading left singular vectors of  $\mathcal{Y}_{(n)}$
- 6 **until** reconstruction error converges or exceeds maximum iteration;
- 7  $\mathcal{G} \leftarrow \mathcal{X} \times_1 \mathbf{A}^{(1)\top} \dots \times_N \mathbf{A}^{(N)\top}$

---

## I. TUCKER ALS ALGORITHM

A widely used technique for minimizing the loss functions Eq. (1) and Eq. (2) of the main paper in a standard tensor factorization is alternating least squares (ALS) [1], which updates a factor matrix or a core tensor while keeping all others fixed.

Algorithm 1 describes a vanilla Tucker factorization algorithm based on ALS, which is called the *higher-order orthogonal iteration* (HOOI) (see [1] for details) that works on fully observable tensor. Notice that Algorithm 1 assumes missing entries of  $\mathcal{X}$  as zeros during the update process (lines 4-5). However, setting missing values to zero enforces Tucker ALS to factorize the original tensor such that missing values becomes zero when reconstructed. Note that the missing values are often nonzero values that are unknown. Thus, setting missing values to zero inserts false information into the factorization which results in higher reconstruction error as well as higher generalization error. Moreover, Algorithm 1 computes SVD (singular vector decomposition) given  $\mathcal{Y}_{(n)}$ , which often results in dense matrices, thus tensor-ALS results in overall dense core tensor and factor matrices. Also, Algorithm 1 requires storing a full-dense matrix  $\mathcal{Y}_{(n)}$ , and the amount of memory needed for storing  $\mathcal{Y}_{(n)}$  is  $O(I_n \prod_{m \neq n} J_m)$ . The required memory grows rapidly when the order, the mode dimensionality, or the rank of a tensor increase, and ultimately causes *intermediate data explosion* [2].

In summary, the vanilla Tucker-ALS algorithm results in high generalization error in the presence of missing data, results in dense and thus hard-to-interpret core tensor and factor matrices, and cannot be applied to large data.

Many tucker factorization algorithms have been developed. Recent works [3]–[5] efficiently update factor matrices and core tensor by dealing with only observed values. However, all of the methods do not consider the sparsity of factor matrices and core tensor. Although Oh et al. [5] truncate noisy entries of core tensor, total sparsity is very small since the size of core tensor is relatively smaller than that of factor matrices. Therefore, Algorithm 1 needs to be revised to focus only on observed entries, make sparse outputs, and be scaled for large-scale tensors at the same time.

## II. PROOFS OF UPDATE RULES AND RESPONSIBILITIES

### A. Proof of Lemma 1 (Updates of Factor Matrices with $L_1$ regularization)

*Proof 1* The partial derivative of  $L_1$  regularization loss function with regard to the factor matrix entry  $a_{ijn}^{(n)}$  is

$$\begin{aligned} \frac{\partial L_1}{\partial a_{ijn}^{(n)}} &= \left[ 2 \sum_{\forall \alpha \in \Omega_{in}^{(n)}} ((\mathcal{X}_\alpha - \sum_{\forall t \neq jn} \delta_\alpha^{(n)}(t) a_{int}^{(n)}) \cdot (-\delta_\alpha^{(n)}(jn))) \right] \\ &\quad + \left[ 2 \sum_{\forall \alpha \in \Omega_{in}^{(n)}} (\delta_\alpha^{(n)}(jn))^2 \cdot a_{ijn}^{(n)} \right] + \lambda \frac{\partial |a_{ijn}^{(n)}|}{\partial a_{ijn}^{(n)}} \\ &= g_{fm} + d_{fm} \cdot a_{ijn}^{(n)} + \lambda \frac{\partial |a_{ijn}^{(n)}|}{\partial a_{ijn}^{(n)}} \\ &= \begin{cases} g_{fm} + d_{fm} \cdot a_{ijn}^{(n)} + \lambda & \text{if } a_{ijn}^{(n)} > 0 \\ g_{fm} + d_{fm} \cdot a_{ijn}^{(n)} - \lambda & \text{if } a_{ijn}^{(n)} < 0 \end{cases} \end{aligned} \quad (2)$$

*Case 1* ( $g_{fm} > \lambda (> 0)$ ) : if  $a_{ijn}^{(n)} > 0$ , then  $\frac{\partial L_1}{\partial a_{ijn}^{(n)}} > 0$  since  $g_{fm} + \lambda > 0$ , and  $d_{fm} > 0$ .  $\frac{\partial L_1}{\partial a_{ijn}^{(n)}} = 0$  when  $a_{ijn}^{(n)} = (\lambda - g_{fm})/d_{fm} (> 0)$ , so that the value of  $\frac{\partial L_1}{\partial a_{ijn}^{(n)}}$  becomes negative when  $a_{ijn}^{(n)} < (\lambda - g_{fm})/d_{fm}$ . In sum,  $L_1$  decreases if  $a_{ijn}^{(n)} < (\lambda - g_{fm})/d_{fm}$ , and increases if  $a_{ijn}^{(n)} > (\lambda - g_{fm})/d_{fm}$ . Thus, the loss becomes minimum when  $a_{ijn}^{(n)} = (\lambda - g_{fm})/d_{fm}$ .

*Case 2* ( $g_{fm} < -\lambda (< 0)$ ) : likewise, if  $a_{ijn}^{(n)} < 0$ , then  $\frac{\partial L_1}{\partial a_{ijn}^{(n)}} < 0$  since  $g_{fm} - \lambda < 0$ , and  $d_{fm} > 0$ .  $\frac{\partial L_1}{\partial a_{ijn}^{(n)}} = 0$  when  $a_{ijn}^{(n)} = -(\lambda + g_{fm})/d_{fm} (> 0)$ , so that the value of  $\frac{\partial L_1}{\partial a_{ijn}^{(n)}}$  becomes positive when  $a_{ijn}^{(n)} > -(\lambda + g_{fm})/d_{fm}$ . In sum, the loss decreases if  $a_{ijn}^{(n)} < -(\lambda + g_{fm})/d_{fm}$ , and increases if  $a_{ijn}^{(n)} > -(\lambda + g_{fm})/d_{fm}$ . Thus, the loss becomes minimum when  $a_{ijn}^{(n)} = -(\lambda + g_{fm})/d_{fm}$  respect to  $a_{ijn}^{(n)}$ .

*Case 3* ( $-g_{fm} < \lambda$ , and  $g_{fm} < \lambda$ ) : If  $a_{ijn}^{(n)} > 0$ , then  $\frac{\partial L}{\partial a_{ijn}^{(n)}} > 0$ ; if  $a_{ijn}^{(n)} < 0$ , then  $\frac{\partial L}{\partial a_{ijn}^{(n)}} < 0$ . In sum, the loss decreases if  $a_{ijn}^{(n)} < 0$ , and increases if  $a_{ijn}^{(n)} > 0$ . Thus, the loss becomes minimum when  $a_{ijn}^{(n)} = 0$ .

### B. Proof of Lemma 2 (Updates of Core Tensor with $L_1$ regularization)

*Proof 2* The partial derivative of  $L_1$  regularization loss function with regard to core tensor entry  $\mathcal{G}_\beta$  is

$$\begin{aligned} & \frac{\partial L_1}{\partial \mathcal{G}_\beta} \\ &= 2 \sum_{\forall \alpha \in \Omega} (\mathcal{X}_\alpha - \sum_{\forall \gamma \neq \beta} \mathcal{G}_\gamma \prod_{n=1}^N a_{i_n j_n}^{(n)} - \mathcal{G}_\beta \prod_{n=1}^N a_{i_n j_n}^{(n)}) (-\prod_{n=1}^N a_{i_n j_n}^{(n)}) \\ & \quad + \lambda \frac{\partial |\mathcal{G}_\beta|}{\partial \mathcal{G}_\beta} \\ &= \left[ -2 \sum_{\forall \alpha \in \Omega} (\mathcal{X}_\alpha - \sum_{\forall \gamma \neq \beta} \mathcal{G}_\gamma \prod_{n=1}^N a_{i_n j_n}^{(n)}) \cdot (\prod_{n=1}^N a_{i_n j_n}^{(n)}) \right] \\ & \quad + \left[ 2 \sum_{\forall \alpha \in \Omega} (\prod_{n=1}^N a_{i_n j_n}^{(n)})^2 \cdot \mathcal{G}_\beta \right] + \lambda \frac{\partial |\mathcal{G}_\beta|}{\partial \mathcal{G}_\beta} \\ &= g_c + d_c \cdot \mathcal{G}_\beta + \lambda \frac{\partial |\mathcal{G}_\beta|}{\partial \mathcal{G}_\beta} = \begin{cases} g_c + d_c \cdot \mathcal{G}_\beta + \lambda & \text{if } \mathcal{G}_\beta > 0 \\ g_c + d_c \cdot \mathcal{G}_\beta - \lambda & \text{if } \mathcal{G}_\beta < 0 \end{cases} \end{aligned} \quad (4)$$

The remaining steps are the same as those of update rule for factor matrices with  $L_1$  regularization (Lemma 1).

### C. Correctness for the Derivation of Responsibility Values of Factor Matrix Entries

*Proof 3* From its definition,

$$\begin{aligned} (RE)^2 \|\mathcal{X}\|_F^2 &= \sum_{\forall \alpha \in \Omega} (\mathcal{X}_\alpha - B(\alpha))^2 \\ &= \sum_{\forall \alpha \in \Omega_{i_n}^{(n)}} (\mathcal{X}_\alpha - B(\alpha))^2 + \sum_{\forall \alpha \notin \Omega_{i_n}^{(n)}} (\mathcal{X}_\alpha - B(\alpha))^2 \\ &= \sum_{\forall \alpha \in \Omega_{i_n}^{(n)}} (\mathcal{X}_\alpha - B_{j_n=j}(\alpha) - B_{j_n \neq j}(\alpha))^2 \\ & \quad + \sum_{\forall \alpha \notin \Omega_{i_n}^{(n)}} (\mathcal{X}_\alpha - B(\alpha))^2 \end{aligned} \quad (6)$$

Note that

$$\begin{aligned} & \sum_{\forall \alpha \notin \Omega_{i_n}^{(n)}} (\mathcal{X}_\alpha - B(\alpha))^2 \\ &= (RE)^2 \|\mathcal{X}\|_F^2 - \sum_{\forall \alpha \in \Omega_{i_n}^{(n)}} (\mathcal{X}_\alpha - B_{j_n=j}(\alpha) - B_{j_n \neq j}(\alpha))^2 \end{aligned} \quad (8)$$

Thus,

$$\begin{aligned} & (RE(a_{ij}^{(n)}))^2 \|\mathcal{X}\|_F^2 \\ &= \left( \sum_{\forall \alpha \in \Omega_{i_n}^{(n)}} (\mathcal{X}_\alpha - B_{j_n \neq j}(\alpha))^2 \right) + \sum_{\forall \alpha \notin \Omega_{i_n}^{(n)}} (\mathcal{X}_\alpha - B(\alpha))^2 \\ &= \left( \sum_{\forall \alpha \in \Omega_{i_n}^{(n)}} (\mathcal{X}_\alpha - B_{j_n \neq j}(\alpha))^2 \right) + (RE)^2 \|\mathcal{X}\|_F^2 \\ & \quad - \sum_{\forall \alpha \in \Omega_{i_n}^{(n)}} (\mathcal{X}_\alpha - B_{j_n=j}(\alpha) - B_{j_n \neq j}(\alpha))^2 \\ &= (RE)^2 \|\mathcal{X}\|_F^2 + \sum_{\forall \alpha \in \Omega_{i_n}^{(n)}} (2\mathcal{X}_\alpha - 2B_{j_n \neq j}(\alpha) - B_{j_n=j}(\alpha))B_{j_n=j}(\alpha) \\ &= (RE)^2 \|\mathcal{X}\|_F^2 + \sum_{\forall \alpha \in \Omega_{i_n}^{(n)}} (2 \cdot (\mathcal{X}_\alpha - B(\alpha)) + B_{j_n=j}(\alpha))B_{j_n=j}(\alpha) \end{aligned} \quad (10)$$

Dividing both sides of Eq. (10) with  $\|\mathcal{X}\|_F^2$ , we get

$$\begin{aligned} & (RE(a_{ij}^{(n)}))^2 \\ &= RE^2 + \frac{\sum_{\forall \alpha \in \Omega_{i_n}^{(n)}} (2(\mathcal{X}_\alpha - B(\alpha)) + B_{j_n=j}(\alpha))B_{j_n=j}(\alpha)}{\|\mathcal{X}\|_F^2} \end{aligned} \quad (12)$$

### III. AN EXAMPLE OF PRUNING BASED ON RESPONSIBILITY

Here we show an toy example of importance of pruning based on responsibility values compared to pruning based on small factor values. Suppose sparse tensor  $\mathcal{X} \in \mathbb{R}^{3 \times 3 \times 3}$ , whose frontal slices is

$$\begin{aligned} \mathcal{X}_1 &= \begin{Bmatrix} & & \\ & & \\ 0.89 & 0.85 & \end{Bmatrix}, \mathcal{X}_2 = \begin{Bmatrix} 0.44 & 0.27 & \\ & 0.88 & \\ 0.47 & & \end{Bmatrix}, \\ \mathcal{X}_3 &= \begin{Bmatrix} 0.48 & 0.14 & \\ 0.95 & 0.40 & \end{Bmatrix}. \end{aligned} \quad (14)$$

where a blank indicates a missing values. The result of  $\mathcal{X}$ 's tucker factorization (implemented by  $\text{VEST}^{man}$  with sparsity  $s = 0$ ) is shown as below ( $RE = 0.12$ ).

$$\begin{aligned} \mathcal{G} &= \{-5.905566\}, \\ \mathbf{A}^{(1)} &= \begin{Bmatrix} -0.33 \\ -0.87 \\ -0.36 \end{Bmatrix}, \mathbf{A}^{(2)} = \begin{Bmatrix} -0.77 \\ -0.48 \\ -0.42 \end{Bmatrix}, \mathbf{A}^{(3)} = \begin{Bmatrix} -0.92 \\ -0.33 \\ -0.23 \end{Bmatrix} \end{aligned} \quad (16)$$

If we prune an element with the smallest absolute value,  $a_{33}^{(3)}$  has to be pruned, leading  $RE = 0.571673$ . On the other hand, if we prune an element with the smallest Resp value,  $a_{11}^{(1)}$  has to be pruned, leading  $RE = 0.37$ . Therefore, the above example indicates that it is better to consider the responsibility rather than simply remove small values.
